## **INTRODUCTION**

A strategy used to improve a lead compound is based on the concept of

bioisosterism. In bioisosterism, the properties of a compound are

fine-tuned by the replacement of some groups or fragments in a

molecule, without affecting its overall biological activity.<sup>1</sup>

#### **AIMS**

• To design molecules binding to the 5-HT receptor using a bioisosteric

approach.

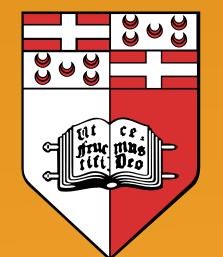

• To compare the affinity of the generated bioisosteres to the affinity of

the endogenous ligands.

### **METHOD**

• Three Tricyclic Antidepressants (TCAs—amitriptyline, imipramine and clomipramine) and three Selective Serotonin Reuptake Inhibitors (SSRIs-

**Department of Pharmacy** 

**University of Malta** 

fluoxetine, paroxetine and sertraline) were selected. Molecular modelling of these structures was carried out in SYBYL-X<sup>®</sup>1.2<sup>2</sup>

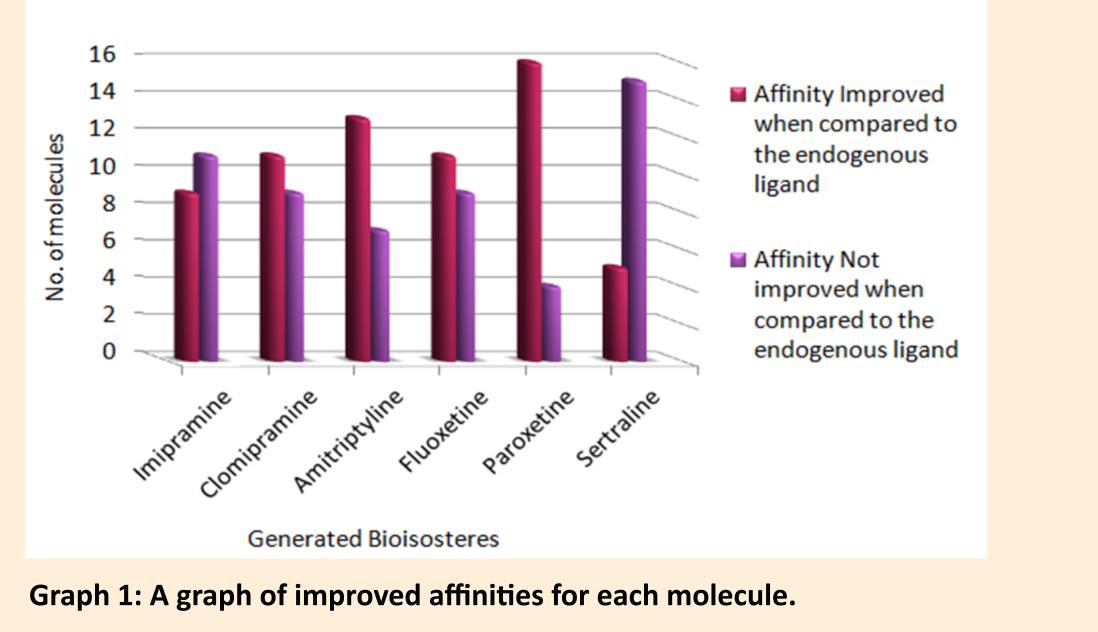

• The Structure Activity Relationships (SARs) of each selected molecule were identified from the literature to identify which moieties on these molecules

were crucial for binding and for eliciting biological activity.

- Using Spark<sup>®</sup>V10<sup>3</sup> software and its molecular databases, 4 different fragments were selected to generate novel ligands which are bioisosteric to the original molecules. The top 5 bioisosteres that had the highest BIF (Bio-Isostere Factor) were chosen for each of the 4 fragments. This process was repeated for every SSRI and TCA molecule.
- The ligand binding affinity (pKd) of the bioisosteric structures for the cognate target receptor was measured in Score<sup>®5</sup> and compared to that of the

## CONCLUSION

The results show that when a bioisosteric approach is used, properties such as the affinity of the ligand binding to the receptor are refined. Further studies

-8.90

-7.86
